AI-ASSISTED USABILITY TESTING 26

Introduction

PROJECT OVERVIEW

The product evaluated in this usability study is the Koenigsegg Automotive website, a luxury hypercar brand platform that emphasizes immersive storytelling, high-end visuals, and engineering innovation. The website functions primarily as a brand experience rather than a traditional e-commerce platform.

CONTEXT FOR THE USABILITY TEST

Previous UX research (competitive analysis, heuristic evaluation, and interviews) identified several usability concerns, including:

- Scroll-heavy navigation
- Difficulty locating technical specifications
- Lack of model comparison tools
- Weak or unclear calls-to-action (CTA)

This usability test was conducted to validate these findings through direct user interaction.

Purpose

RESEARCH OBJECTIVES

The objective of this study is to evaluate how effectively users can:

- Navigate the website
- Locate key information (e.g., specs)
- Complete important tasks (e.g., contacting a dealer)
- Understand the next steps in the user journey

CONTEXT FOR THE USABILITY TEST

- Can users easily find technical specifications?
- How efficient is navigation across long pages?
- Do users struggle to compare models?
- Is the purchase/inquiry pathway clear?
- What usability issues impact overall experience?

User Profiles

Four participants were recruited, representing target users aged 18–20.

The users are a mix of:

Automotive Enthusiasts

Casual users

Design-focused Users

Technical users

Participants had varying familiarity with automotive websites, reflecting realistic users identified in prior research

Methodology & Environment

TESTING APPROACH

The study used a moderated usability testing approach, where a facilitator guided participants through a series of predefined tasks while observing their interactions and behaviors. A "think-aloud" method was employed, encouraging users to verbalize their thoughts, expectations, and decision-making processes in real time, providing deeper insight into usability issues. Each session lasted approximately 20 minutes, allowing sufficient time to complete tasks while capturing meaningful feedback on the overall user experience.

TOOLS & ENVIRONMENT

The usability testing was conducted remotely using the mobile app Zoom, allowing participants to join from their own environments. Sessions were carried out on both desktop and mobile devices to capture a range of user experiences, using commonly used browsers such as the software Google Chrome and the software Safari. Throughout the sessions, observations and user feedback were documented through manual note-taking to ensure key insights and usability issues were accurately recorded.

Methodology & Environment

ETHICAL CONSIDERATIONS

Ethical considerations were carefully addressed throughout the study, with informed consent obtained from all participants prior to testing. No personal data was collected during the sessions, and participants were anonymized using identifiers (P1–P4) to protect their identities. Additionally, no session recordings were stored, ensuring participant privacy and confidentiality were maintained at all times.

USE OF AI

Generative AI was used to support the development process by helping structure the test plan, organize findings into a clear and logical format, and refine the overall clarity and readability of the report. Its role was limited to enhancing presentation and organization, while all testing, evaluation, and analysis were conducted manually to ensure accuracy and validity of the results.

Task List

1. **Find technical specifications**
   Measure efficiency of locating key data

2. **Compare two models**
   Measure efficiency of locating key data

3. **Find dealer/contact info**
   Test clarity of CTA

4. **Navigate to engineering info**
   Assess navigation clarity

5. **General exploration**
   Capture overall impressions

Key Usability Issues

1: INEFFICIENT ACCESS TO SPECIFICATIONS

Inefficient Access to Specifications Users consistently had to scroll excessively to find technical specifications, as this information was located at the bottom of pages. This led to noticeable frustration, particularly among technical users who expected quick and easy access to detailed information.

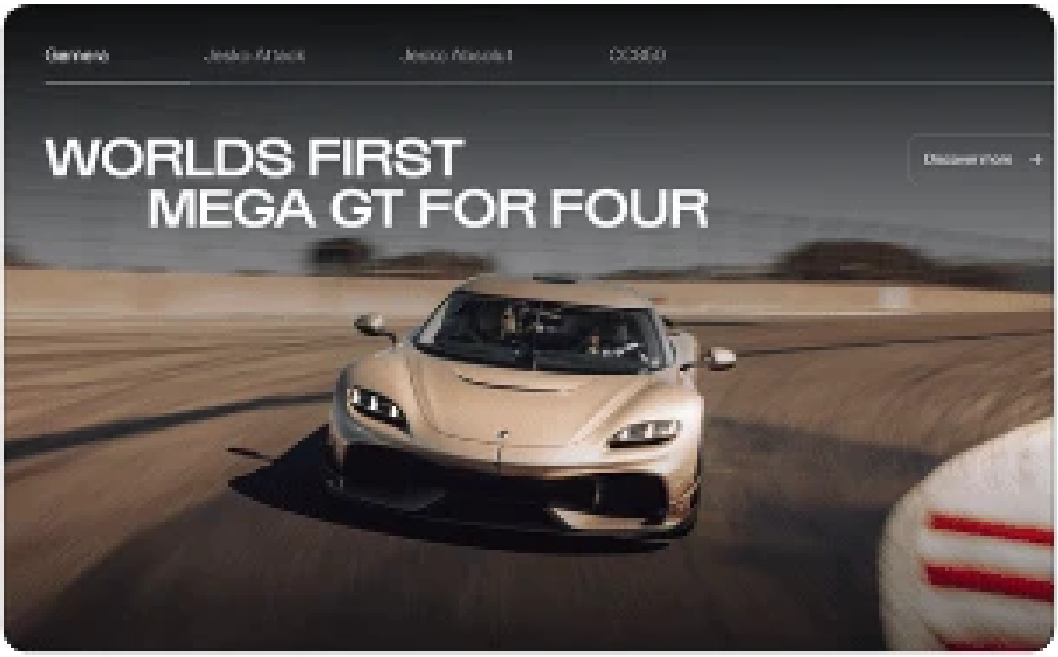

* Takes a lot of scrolling just to get to the specifications section.

Key Usability Issues

2: NO MODEL COMPARISON FEATURE

Lack of Model Comparison Feature Users were forced to open multiple tabs to compare different models, making it difficult to remember and evaluate key specifications across pages. This increased cognitive load and made the comparison process inefficient and frustrating

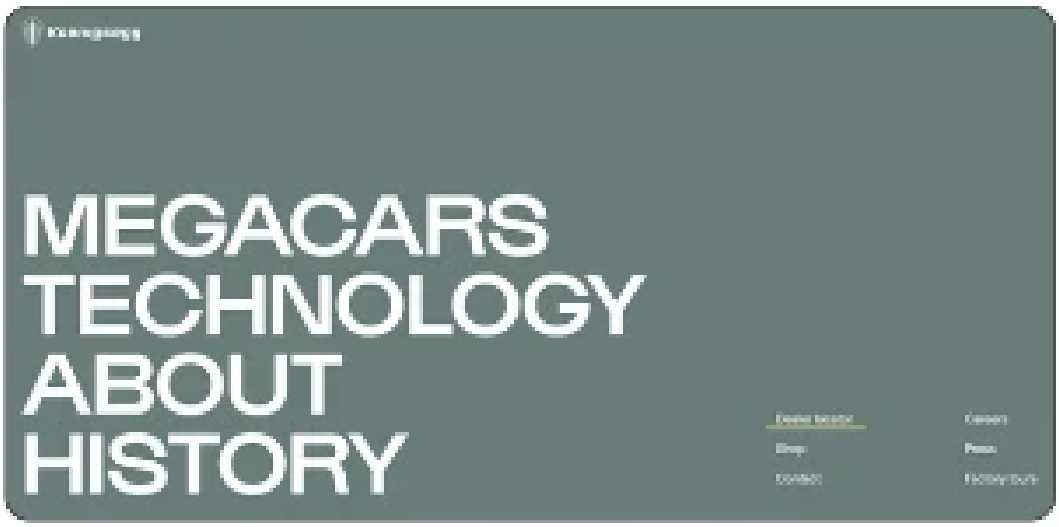

There is no compare option only a button to discover more about the model

Key Usability Issues

3: WEAK OR HIDDEN CALL-TO-ACTION

Unclear Call-to-Action ("Find Dealer") The "Find Dealer" option was difficult for users to locate, as it was placed in the footer, leading to confusion about how to proceed. As a result, users were often unsure of the next step, highlighting a lack of clear and effective guidance in the user journey.

the only call-to-action that is apparent in the site is "Dealer location," which is not clearly visible in the site or when looking at a certain car model.

Key Usability Issues

4: SCROLL-HEAVY NAVIGATION

Poor Navigation on Long Pages Users frequently lost their orientation when navigating long, scroll-heavy pages, as there were no shortcuts or anchor links to help them move efficiently between sections. This resulted in increased cognitive fatigue, particularly for mobile users who found continuous scrolling more tedious.)

Almost every page has scrolling animations.

Key Usability Issues

5: ACCESSIBILITY ISSUES (TEXT CONTRAST)

Accessibility Issues (Text Contrast): Text placed over images was often difficult to read due to low contrast, reducing overall readability for some users and potentially limiting accessibility for those with visual impairments

In the safety systems page, the descriptive text color does not contrast well with the background.

Usability Metrics

METRIC	RESULT
Task Success Rate	65%
Failure Rate	35%
Average time on task	~ 2-4 minutes
Error Frequency	Moderate

BREAKDOWN

- Task 1 (Specs): Medium success, high time
- Task 2 (Compare): Low success
- Task 3 (CTA): Low success
- Task 4 (Navigation): Medium success
- Task 5 (Explore): High success

Recommendations for Improvement

ADD STRUCTURED SPECIFICATION TABLES

HIGH

Add Structured Specification Tables: Present technical specifications in clearly organized, structured tables to make information more visible and easy to scan, reducing the need for excessive scrolling and improving overall usability

A good addition is adding specifications at the start of the page when a user explores a model so they dont have to scroll too far and it is eaily visible.

15

Recommendations for Improvement

INTRODUCE MODEL COMPARISON TOOL

HIGH

Introduce a Model Comparison Tool: Provide a side-by-side comparison feature that allows users to evaluate multiple models simultaneously, making it easier to identify differences and reducing cognitive load.

Current & Recent Model Comparison

Model	Type	Engine/Powertrain	Peak Power (ESS)	Top Speed (Claimed/Tested)
Jesko Absolut	High Speed	5.0L Twin-Turbo V8	1,600 hp	330+ mph (Theoretical)
Jesko Attack	Track	5.0L Twin-Turbo V8	1,600 hp	310 mph
Gemera (HV8)	4-Seat GT	5.0L V8 + Electric	2,300 hp	250+ mph
CC850	Heritage	5.0L Twin-Turbo V8	1,385 hp	300+ mph (Theoretical)
Regera	Luxury GT	5.0L V8 Hybrid (KDD)	1,500 hp	250 mph

This is an example of how they should have a list on the comparison table on the megacars page so users could compare the models.

Recommendations for Improvement

MAKE "FIND DEALER" A PRIMARY CTA

HIGH

Improve Call-to-Action Visibility: Move key actions such as "Find Dealer" to the main header or primary navigation area and present them using a clear, visually prominent button design to make the next steps in the user journey more obvious and accessible.

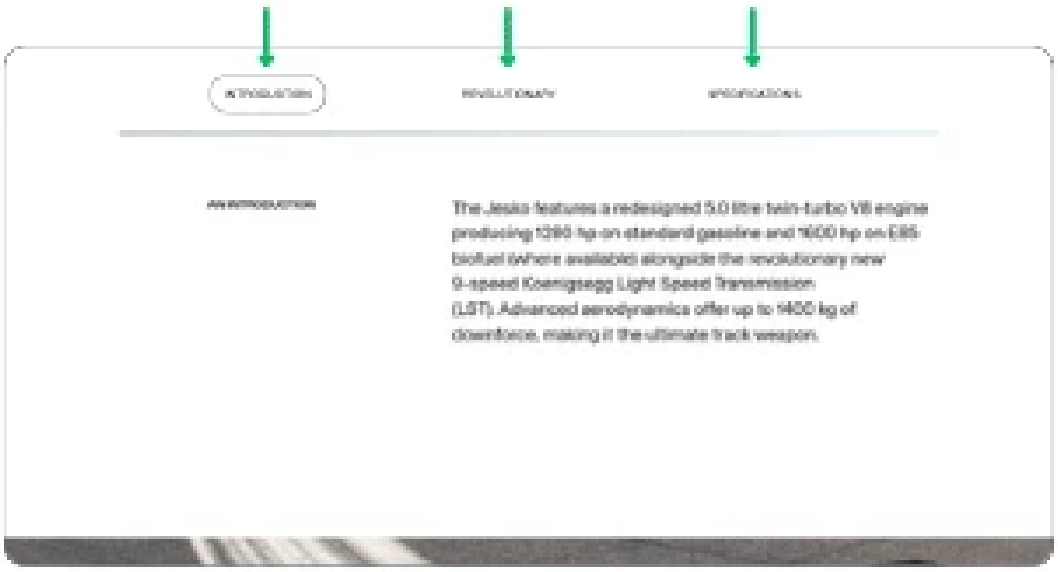

This is an example of how a CTA should be visible on the title page of a specific car model.

Recommendations for Improvement

ADD ANCHOR NAVIGATION

MEDIUM

Implement anchor links that allow users to jump directly to key sections such as Specifications, Engineering, and Gallery, improving navigation efficiency and reducing the need for excessive scrolling.

This is an example of how anchor links can be implimented.

Recommendations for Improvement

IMPROVE TEXT CONTRAST

MEDIUM

Adding overlays or shadows behind text placed on images improves readability by creating consistent contrast and reducing background noise that can obscure the text. Semi-transparent overlays help normalize brightness variations, while subtle text shadows enhance edge definition, making content easier to distinguish even on complex visuals.

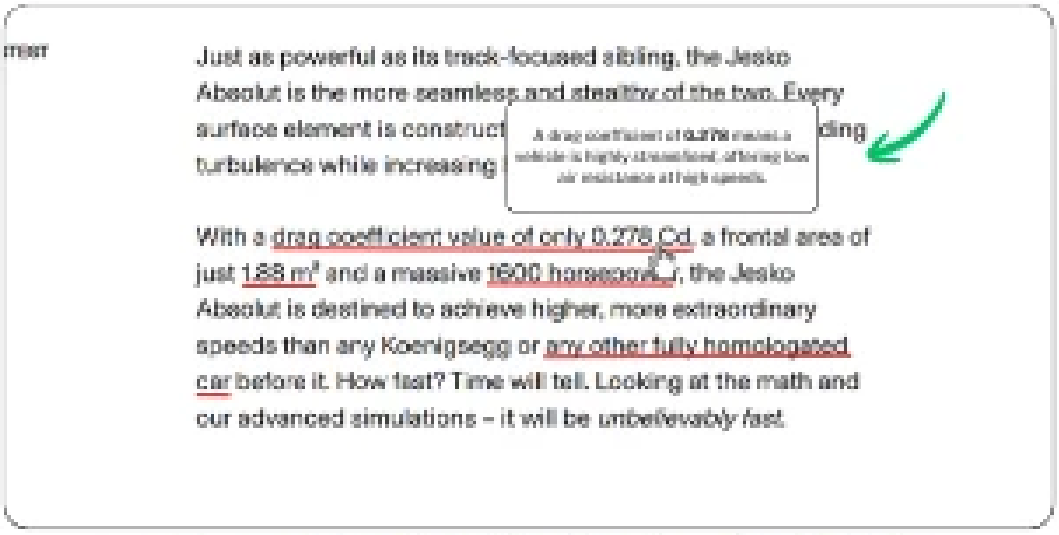

This is an example of good text placement so that the sentence clearly contrasts well with the dark shadow on the background.

Recommendations for Improvement

ADD TOOLTIPS FOR TECHNICAL TERMS

LOW

Providing guided assistance through contextual help and tooltips enables non-expert users to better understand complex information without overwhelming them. By offering brief, on-demand explanations at the point of interaction, users can learn as they navigate, reducing confusion and increasing confidence in completing tasks.

This is a example of providing tooltips [indicated by underlined text while hovering] can help users identify context and understand better.

Themes Identified

VISUAL APPEAL VS USABILITY

Users consistently praised the website's visual design, citing its aesthetics, imagery, and overall style as engaging and modern.

However, this strong focus on visuals often compromised usability, as important information was harder to locate; navigation became more cumbersome. Completing key tasks like finding specifications or comparing models required extra effort. This highlights a tension between creating an attractive design and maintaining an efficient, user-friendly experience.

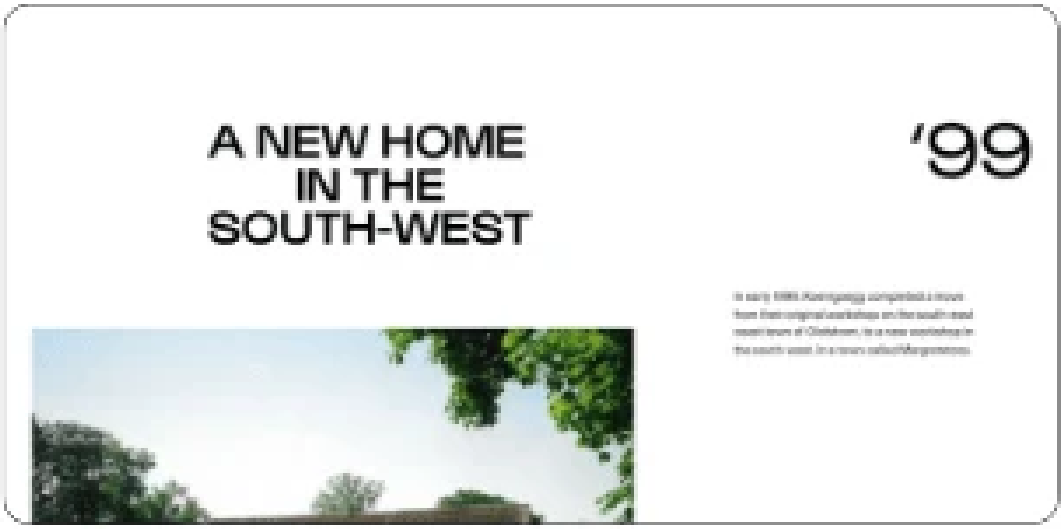

Themes Identified

EFFICIENCY ISSUES

Users frequently experienced delays due to excessive scrolling and the scattered placement of important information.

Key content, such as technical specifications and comparison data, was difficult to access quickly, which reduced task efficiency and increased user frustration, especially on mobile devices.

Themes Identified

LACK OF TASK SUPPORT

Users struggled to complete critical tasks because the website lacked essential support features.

The absence of model comparison tools made evaluating options cumbersome, and unclear calls-to-action left users uncertain about the next steps in their journey, hindering task completion and overall satisfaction.

Themes Identified

NAVIGATION FRICTION

Users often lost their sense of location on long, scroll-heavy pages due to a lack of navigational aids.

Without shortcuts, anchor links, or clear section markers, users experienced disorientation and increased effort when trying to access specific content, particularly on mobile devices.

Themes Identified

ACCESSIBILITY CONCERNS

Users encountered difficulties reading text, especially when it was placed over images with low contrast.

These readability issues reduced accessibility for some users and highlighted the need for design adjustments to meet inclusive standards and improve overall legibility.

AI-Assisted Usability Testing

OVERVIEW

To supplement the manual usability testing sessions conducted with four participants (P1–P4), an AI-assisted evaluation was performed on the Koenigsegg Automotive website. This involved using a generative AI system (Claude, Anthropic) as a simulated evaluator to independently audit the site's usability, validate patterns from the human sessions, and surface any additional issues that may have been missed due to the limited participant sample size.

The AI evaluation was structured to mirror the same five tasks given to human participants, enabling a direct comparison between simulated and observed behaviours. All AI-generated insights were reviewed and cross-referenced against manual findings to ensure relevance and accuracy.

AI Testing Methodology

APPROACH

The AI evaluator was provided with a detailed description of the Koenigsegg website's structure, navigation patterns, visual design choices, and interaction flows, derived from the same environment used in human testing. It was then asked to simulate user behaviour across each of the five tasks, documenting predicted pain points, likely error paths, and moments of confusion.

TOOLS & SETUP

AI System Used	Claude (Anthropic) — Conversational LLM
Evaluation Mode	Simulated task walkthrough + heuristic analysis
Input Provided	Site structure description, screenshots, task scenarios
User Archetypes Simulated	4 (matching human participant profiles)
Tasks Evaluated	5 (identical to human test task list)
Cross-reference	Findings compared against P1–P4 session notes

AI Evaluation: Task-by-Task Findings

1: FIND TECHNICAL SPECIFICATIONS

The AI evaluator, simulating both the Technical User and the Automotive Enthusiast, predicted significant difficulty locating specifications without prior knowledge of the page layout. The immersive scroll experience on individual model pages means that specification data is positioned deep into the content flow, well below the hero section and narrative copy.

This matches findings from P2 and P3, both of whom took over 3 minutes on Task 1 and verbally expressed frustration at not knowing how far they needed to scroll.

HIGH

AI Severity Rating: Estimated task completion time for a cold user: 3–5 minutes without anchor navigation.

AI Evaluation: Task-by-Task Findings

2: COMPARE TWO MODELS

The AI evaluator, operating from the perspective of a Casual User, noted the complete absence of any comparative interface across the Megacars section. Models are presented sequentially with individual "Discover More" buttons, providing no mechanism for side-by-side evaluation.

The AI also flagged that even the specification formats between model pages are not fully standardized, meaning that even if a user navigated between pages, the data fields do not align consistently, further complicating comparison.

This directly corroborates the low success rate recorded for Task 2 across all four human participants. The AI went further, identifying the inconsistent spec formatting as a secondary issue not captured in the manual sessions.

HIGH

AI Severity Rating: Feature gap; no comparison tool exists in any form.

AI Evaluation: Task-by-Task Findings

3: FIND DEALER / CONTACT INFORMATION

Simulating the Casual User archetype, the AI predicted that the "Dealer Locator" option would be overlooked by most visitors. The navigation structure buries this option in the footer alongside secondary links such as Careers, Press, and Factory Tours — none of which suggest a conversion pathway.

The AI additionally observed that individual model pages contain no persistent "Find Dealer" or "Enquire" button — a significant gap for users who reach a buying decision while browsing a specific car.

Human sessions confirmed this: P1 and P4 both failed to locate the dealer contact option without assistance. P2 found it only after navigating to the footer by accident.

HIGH

AI Severity Rating: Direct impact on business conversion goals.

AI Evaluation: Task-by-Task Findings

4: NAVIGATE TO ENGINEERING INFORMATION

The AI evaluator, simulating the Design-Focused User, noted that the top-level navigation label "Technology" does serve as a reasonable entry point to engineering content. However, the scroll-triggered animations within these pages introduce a pace mismatch — users who want to quickly consume technical information are forced through a cinematic experience designed for slower, more atmospheric browsing.

Medium task success was observed in human sessions for this task, consistent with the AI's prediction that navigation is possible but slow. P3 and P4 both completed the task but rated the experience as frustrating.

MEDIUM

AI Severity Rating: Navigation path exists but is obstructed by interaction design.

AI Evaluation: Task-by-Task Findings

5: GENERAL EXPLORATION

The AI evaluator acknowledged that the Koenigsegg website excels at creating an immersive brand experience. For users approaching the site without a specific goal, the visual quality, full-screen imagery, and narrative-driven content produce a highly engaging encounter.

All four human participants rated the visual design positively during Task 5 (general exploration), validating the AI's assessment that aesthetic quality is a strength. The tension identified is between the immersive brand layer and the functional task laye, not an either/or problem, but one of balance.

LOW

AI Severity Rating: Strong brand experience; usability gaps are structural, not aesthetic.

AI vs. Human Testing: Comparative Summary

The table below summarizes how AI-simulated findings align with or extend the results observed in human usability sessions.

Task	Human Session Finding	AI Evaluation Finding
Task 1: Find Specs	Medium success; high time on task	Predicted 3–5 min; scroll depth is primary barrier
Task 2: Compare Models	Low success; users opened multiple tabs	Confirmed gap; flagged inconsistent spec formats (new finding)
Task 3: Find Dealer CTA	Low success; CTA buried in footer	Confirmed; noted absence of CTA on individual model pages (new finding)
Task 4: Engineering Nav	Medium success; slow but possible	Confirmed; scroll-jacking cited as pace mismatch for task users
Task 5: General Explore	High success; visual design praised	Confirmed; framed tension as information architecture vs. brand layer

Additional Findings from AI Evaluation

Beyond the five structured tasks, the AI evaluator was asked to conduct a broader heuristic review of the site against Nielsen's 10 Usability Heuristics. Two issues were identified that were not surfaced prominently in the manual sessions:

1. LACK OF SYSTEM STATUS VISIBILITY

The scroll-triggered animations do not provide any loading indicator or progress feedback. On slower connections, content sections may appear blank momentarily before animating in, with no visible signal that content is incoming. This violates Heuristic 1 (Visibility of System Status) and could cause users to believe a page has failed to load.

2. NO SEARCH FUNCTIONALITY

The site contains no global search bar. A user looking for a specific technology (e.g., "Light Speed Transmission") or a specific model (e.g., "CC850") has no direct retrieval path. This is particularly impactful for returning visitors or researchers who know what they are looking for. The AI rated this as a medium severity issue that would disproportionately affect Technical Users.

Ethical Use Statement

The AI-assisted usability evaluation was conducted as a supplementary method only. No AI-generated findings were presented as primary research data without cross-referencing against the four human participant sessions. The AI system was used as a structured analysis tool to extend coverage, not to replace the lived experience and think-aloud insights of real users.

All interpretations, severity ratings, and design recommendations in this report were reviewed and validated by the research team. Where AI findings diverged from human session observations, the human data was treated as authoritative.

The use of AI in this study reflects current industry practice in UX research, where AI tools are increasingly employed for heuristic audits, pattern recognition, and gap analysis — while human-centred methods remain the foundation of valid usability findings.
